

Trading Options Around Earnings

OPTIONS WEBINAR: APRIL 28, 2022

What is on our agenda today?

Researching Earnings

How to find and screen for securities with upcoming earnings

Volatility

What are implied and historical volatility and how do they impact your trade

Options Strategies

Which strategies can be considered for a potential earnings trade

Expected move

How to estimate an expected move for earnings announcements

Volatility

Historical vs. Implied volatility

Historical volatility (HV)

- Uses *actual* pricing data over the specified period
- Measure of *realized* volatility
- Can be gauged by looking at a price chart
- Based on number of trading days – i.e. HV20 includes 20 trading days worth of data

Volatility

Historical vs. Implied volatility

Implied volatility (IV)

- Derived from the option contract prices on the given security
- Measure of future expected movement
- Based on calendar days for a theoretical option i.e. IV30 is for 30 calendar days

Volatility is both an input for, and an output from, option theoretical pricing models such as Black Scholes, Binomial, and others

- HV is considered when pricing the initial IV in the contract
- Estimate of IV can be derived by working backwards through the formula since the option's price and all other components are known

Volatility

Implied Volatility

- Measures what the market “expects” volatility of the security to be in the future, based on premiums for option contracts on that security
- Annualized percentage for future expected move
- Dynamic - will change with option prices based on supply and demand for contracts

VOLATILITY			
IV30 62.35	IV60 65.63	IV90 65.48	
HV10 28.05	HV20 30.24	HV30 45.02	HV60 47.97

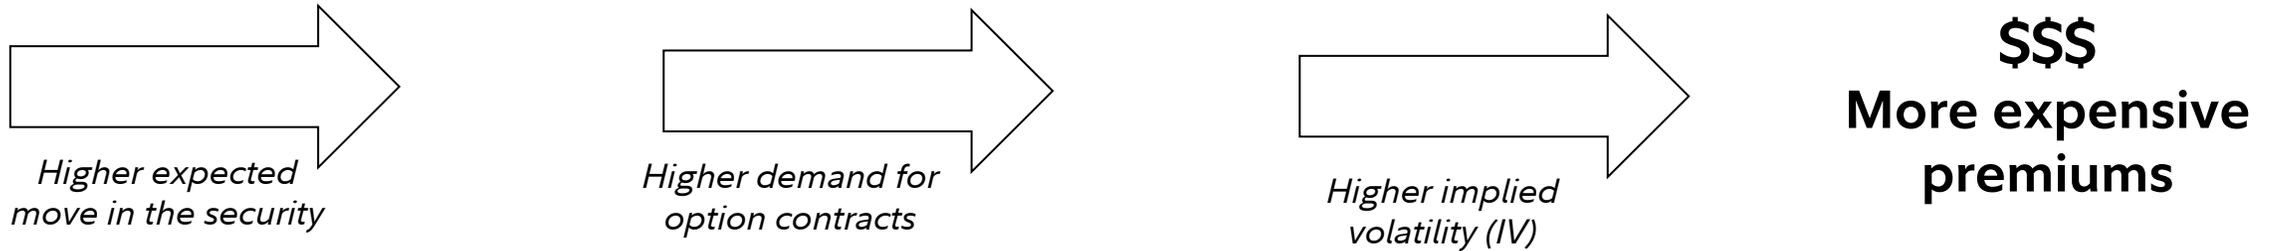

Image shows volatility data from the option statistics tool in Active Trader Pro

62.35% annualized expected move based on hypothetical 30 day option contracts

Volatility

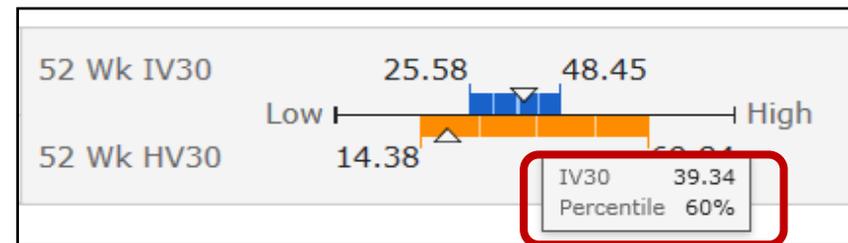

Implied Volatility

IV is a product of supply and demand for option contracts, and therefore has an affect on option prices. It can be a measure of relative expensiveness.

How can you determine whether a specific stock's IV is relatively expensive (or inexpensive?)

IV percentile shows where a specific stock's IV is compared to where it has been within the last 52 weeks.

IV percentile can be found in the option statistics feature on ATP.

Volatility

Implied Volatility

IV index chart compares historical volatility (HV) with implied volatility (IV) over the last year and can be found in the options research on [Fidelity.com](https://www.fidelity.com)

How can you determine whether a specific stock's IV is relatively expensive (or inexpensive?)

- Helps to compare current volatility data with historical data to identify potentially high or low levels
- Allows traders to identify divergence and convergence between HV and IV
- Quick way to find when volatility measures could be at extremes and may revert to their mean values
 - Keep in mind that the mean could potentially change to that extreme level.

Expected move calculation

Many traders will convert the annualized expected move into daily expected move or expected move until expiration using the following formula:

$$\text{One standard deviation move} = \frac{\text{Stock Price} \times \text{Implied Volatility} \times \sqrt{\text{Days to expiry}}}{\sqrt{\text{Trading Days in a year}}}$$

Hypothetical example of how to calculate the daily expected move...

Stock price = \$100

IV = 20%

Sq. root of trading days in a year = approx. 16

$$\frac{\$100 \times .20 \times 1}{16} \quad + \text{ or } (-) \quad \$1.25$$

Something helpful to remember is 16% IV results in a 1% daily expected move

For example: Stock price = \$100 IV = 16%

[\$100 x .16 x 1]/16 = +/- \$1

Impact on Option Prices

Q: Which option Greek measures the impact of implied volatility (IV) changes on an option contract's value?

A: Vega estimates the amount an option contract will change due to a 1% move in IV

Let's look at an example...

Strike	Bid	Ask	Vega
78.5	3.55	3.70	0.0525
79	3.30	3.40	0.0531
79.5	3.05	3.10	0.0534
80	2.83	2.87	0.0535
80.5	2.60	2.64	0.0533

Vega = .0535

Theoretically, the option will make \$5 per contract with each 1% move up in IV, and lose \$5 per contract with each 1% move down in IV.

Example:

You are predicting a 8% drop in IV after an earnings announcement.

$$-8 \times .0535 \times 100 = \text{\$42.80 / contract}$$

You are expecting the contract price to go from **2.83 to 2.40** (2.83 - .428) resulting in a **loss of \$42.80 from the 8% IV drop**, if everything else remained constant.

Volatility Crush and Vega

Last	Chg	Bid	Ask	Volume	Open Int	Vega	IV Mid	Strike	Last	Chg	Bid	Ask	Volume	Open Int	Vega	IV Mid
CALLS Mar 24 PUTS																
2.34	0.01	2.30	2.40	1,896	1,337	0.0187	97.12 %	64	1.44	-0.15	1.29	1.40	3,548	471	0.0186	92.25 %

CALLS Mar 24 PUTS																
0.07	-2.27	0.05	0.10	313	1,682	0.0068	40.97 %	64	1.98	0.54	1.85	2.02	2,569	3,606	0.0041	32.27 %
0.05	-2.03	0.05	0.10	143	1,299	0.0062	48.68 %	64.5	2.40	0.81	2.10	2.50	69	721	0.0063	41.39 %
0.05	-1.76	0.04	0.05	855	13,214	0.0044	49.69 %	65	2.67	0.79	2.77	2.99	134	878	0.0062	33.23 %
0.04	-1.51	0.03	0.04	140	4,364	0.0035	53.09 %	65.5	3.67	1.62	3.00	3.65	7	186	0.0077	58.22 %
0.04	-1.25	0.02	0.05	189	1,926	0.0033	58.95 %	66	3.90	1.52	3.55	4.00	7	159	0.0053	46.86 %

Volatility on the Calls:

IV Mid was 92.88% with Vega at \$0.0193

IV Mid ended up at 49.69%

Option Value Lost due to Volatility = $92.88\% - 49.69\% = 43.19\% * \$0.0193 = \text{about } \$0.83$

Volatility on the Puts:

IV Mid was 94.38% with Vega at \$0.0193

IV Mid ended up at 33.23%

Option Value Lost due to Volatility = $94.38\% - 33.23\% = 61.15\% * \$0.0193 = \text{about } \$1.18$
